--

In the short time that gas fracking exists in Australia and overseas, there have already massive shortcomings of that technology emerged. They are so severe and detrimental to the health and wellbeing of the effected communities that a permanent stop of all ongoing and potential projects is called for.

Problems include: contamination of water, soil and air.

Fracking chemicals not being compatible with organic agriculture or any other clean food production methods. Interruption of normal income generating agricultural activities. High volumes of carbondioxide and potentially other noxious gases released into the environment and contributing to Climate Change. It is extremely shortsighted to follow up with that technology and by doing so endangering a valuable local industry.

There are many benign energy sources already available to meet the local energy demand and there will be even more in the distant future. There is absolutely no need to indulge in dangerous undertakings that may be profitable for very few and dangerously detrimental for many.
